ABSTRACT

An examination of the Wald stopping bounds for the Sequential Probability Ratio Test (SPRT) is made by comparing results obtained from Monte Carlo simulations of sequential sampling tests with results obtained using Wald formulations. Operating Characteristic, ASN, and $V[N]$ values are presented for tests sampling from each of eight Binomial, 14 Exponential, and 24 Normal distributions. An extensive bibliography of references associated with SPRT is included.

PREFACE AND ACKNOWLEDGEMENTS

The terms "approximate" and "exact" used in this thesis are associated with the Wald derivation of the SPRT and the author's Monte Carlo simulation model of a SPRT procedure, respectively. These terms are used only to distinguish between the two sources of results.

The computer programs were tested at the Naval Postgraduate School's Computer Center in the period from March 1969 to January 1970. All references in this thesis to times and other computer items are related to this IBM-360 computer.

I wish to express my sincere appreciation to Professor Donald R. Barr, to the personnel at the library of the Naval Postgraduate School, and to the computer facility and its staff.

I. OBJECTIVE

In this thesis the accuracy of the Wald approximate decision limits of the Sequential Probability Ratio Test (SPRT) are investigated. The Wald approximate limits are compared with "exact" empirical limits obtained by Monte Carlo simulation. An extensive bibliography of references associated with the SPRT is included.

II. HISTORY OF SPRT

In statistical theory the size of a sample may or may not be fixed prior to observation of certain sample values. If, in a test of hypotheses, the sample size is not fixed in advance, the decision to terminate sampling may depend upon the values of the previous samples. Such a test is said to be sequential.

The first mention of sequential test procedures was by H. F. Dodge and H. G. Romig who, in 1929, constructed a Double Sampling Plan. Prior to World War II, there are not many entries in the literature concerning sequential procedures. During World War II the Statistical Research Group of Columbia University operated under a contract with the Office of Scientific Research and Development and was directed by the Applied Mathematics Panel of the National Defense Research Committee. Milton Friedman and W. Allen Wallis, members of the research group, recognized the great potentialities and far reaching consequences that sequential analysis might have; consequently various members of the group, and in particular A. Wald, worked out what is known as the SPRT. In the early 1940's many of these results were classified, however, the Restricted classification was removed in 1945.

Abraham Wald, in 1943, worked out the basic principles for the SPRT [Wald, 1943]. During the next two years Wald continued working on the basic principles of the SPRT,

including a general consideration of cumulative sums of independent random variables which gives the Operating Characteristic (OC) curve of any SPRT, and the characteristic function of the number of observations required by the test [Wald, 1944].

During this same period of time, independent work on sequential inferences was also conducted in England by G. A. Barnard [Barnard, 1946] who derived general results similar to those obtained by the Statistical Research Group at Columbia.

Since the unfortunate death of A. Wald in 1950, there have been many varied contributions to the literature of sequential methods. These contributions tend to deal primarily with specific families of distributions. Many of the articles are listed in the bibliography.

III. THEORETICAL BACKGROUND OF THE SPRT

The Sequential Probability Ratio Test of a simple Null Hypothesis against a simple Alternate Hypothesis differs from fixed sample size hypothesis tests in that it is conducted in stages, where a stage constitutes evaluation of an observation. At each stage one of three alternatives is chosen: (1) discontinue sampling, accept the null hypothesis; (2) discontinue sampling, reject the null hypothesis; (3) draw another observation. The procedure continues until one of the alternatives (1) or (2) is chosen. Under quite general assumptions, the probability of eventual termination of the SPRT is equal to one.¹

A. DEFINITION OF SPRT

Let the distribution of the random variable, X , under consideration be given by the density or mass function, $f(x; \theta)$. Let H_0 be the Null Hypothesis that $\theta = \theta_0$ and H_1 be the Alternate Hypothesis that $\theta = \theta_1 > \theta_0$. Therefore the density or mass function of X will be $f(x; \theta_0)$ when H_0 is true and $f(x; \theta_1)$ when H_1 is true. Successive independent observations on X will be denoted x_i , $i = 1, 2, \dots$. The SPRT is based on the likelihood ratio,

$$\Pi_n = \frac{\prod_{i=1}^n f(x_i; \theta_1)}{\prod_{i=1}^n f(x_i; \theta_0)}$$

¹A. Wald, Sequential Analysis, Wiley, N.Y., 1947, p.157.

and two positive numbers A and B, $A > 1$ and $B < 1$. After each observation on X, the procedure for choosing one of the three alternatives is:

- 1) if $\Pi_n \leq B$, Discontinue Sampling, Accept H_0
- 2) if $\Pi_n \geq A$, Discontinue Sampling, Accept H_1
- 3) if $B < \Pi_n < A$, Draw another observation.

B. DERIVATION OF STOPPING BOUNDS

The two constants A and B are determined so that the test will have (nearly) the prescribed probabilities, α and β , of making errors, where α is the probability of making a Type I error (Rejecting H_0 when it is true) and β is the probability of making a Type II error (Accepting H_0 when it is false). Exact values for A and B could, in principle, be obtained from the following equations given in the first that H_0 is true and in the second that H_1 is true:

$$\alpha = P[\Pi_1 \geq A] + P[\Pi_2 \geq A, B < \Pi_1 < A] + \dots$$

$$\beta = P[\Pi_1 \leq B] + P[\Pi_2 \leq B, B < \Pi_1 < A] + \dots$$

In practice, approximations for A and B developed by Wald are usually used, where α and β are specified apriori.² The Wald approximate stopping bounds are

$$A = \frac{1 - \beta}{\alpha}$$

$$B = \frac{\beta}{1 - \alpha} \quad .$$

²A. Wald, Sequential Analysis, op.cit., pp. 40-44.

The boundaries used in the tests performed for this thesis were formulated as two diagonal lines with proper intercepts.³ These boundaries are called the acceptance number, A_n , and the rejection number, R_n . These numbers are obtained by setting the logarithm of Π_n , the likelihood ratio, equal to the logarithms of A and B. The resulting test is the Wald SPRT with stopping bounds A and B.

C. RANDOM WALK OF THE OBSERVATION RESULTS

At each observation the value of the test statistic was tabulated. The stepwise values of the test statistics can be graphed with the abscissa being the number, n , of observations made and the ordinate being the value of the test statistic. The boundaries, A_n and R_n , will limit the steps of the random walk. The test terminates when either boundary is reached or surpassed by a value of the test statistic.

D. THE OC FUNCTION OF THE SPRT

The Operating Characteristic (OC) Function, $L(\theta)$, is defined as the probability that the sequential test will lead to acceptance of H_0 when θ is the true value of the parameter. Using the approximations on the stopping

³A. Wald, "Sequential Tests of Statistical Hypothesis," Annals of Math. Stat., Vol. 16, No. 2, 1945, pp. 160-62.

bounds mentioned above, Wald showed⁴ that the OC function could be approximated by

$$L(\theta) \doteq \frac{A^{h(\theta)} - 1}{A^{h(\theta)} - B^{h(\theta)}} \quad (1)$$

where $h(\theta)$ is a non-negative real number such that

$$\int_{-\infty}^{\infty} \frac{f(x; \theta_1)}{[f(x; \theta_0)]^{h(\theta)}} f(x; \theta) dx = 1, \quad (2)$$

or the equivalent summation in the case f is a mass function.

It is sometimes difficult in practice to obtain the value for $h(\theta)$ for each of various given values of θ , in such cases a "reverse" process may be used: set $h(\theta)$ equal to a non-zero real number and compute a corresponding value of θ . This technique was used in computing $L(\theta)$ for the Binomial and Exponential distributions in this thesis.

E. THE EXPECTED SAMPLE SIZE OF THE SPRT

As mentioned above, with probability one the SPRT eventually terminates. Thus, using the approximate boundaries, A and B , and disregarding the "excess" of Π_n over these boundaries at termination,

$$P[\text{Ln } B = Z \mid \theta] \doteq L(\theta)$$

$$P[\text{Ln } A = Z \mid \theta] \doteq 1 - L(\theta)$$

⁴A. Wald, Sequential Analysis, op.cit., pp. 48-52, 161-64.

where $Z = \sum_{i=1}^N \ln \Pi_i = \sum_{i=1}^N Z_i$, and where in turn N is the sample size required for termination. Therefore, the conditional expected value of Z , given θ , is approximately

$$E[Z | \theta] \doteq [1-L(\theta)] \ln A + L(\theta) \ln B .$$

Utilizing Wald's Fundamental Identity,⁵ the conditional expected value of Z , given θ , can be written

$$E[Z | \theta] = E\left[\sum_{i=1}^N Z_i | \theta\right] = [E]N \quad E[Z_1 | \theta] .$$

The Expected Sample Size for the test is therefore given approximately by

$$E[N] = \frac{E[Z | \theta]}{E[Z_1 | \theta]} \doteq \frac{[1-L(\theta)] \ln A + L(\theta) \ln B}{E[Z_1 | \theta]} . \quad (3)$$

If $E[Z_1 | \theta] = 0$, one may approximate the Expected Sample Size by

$$E[N] = \frac{E[Z^2 | \theta]}{E[Z_1^2 | \theta]} . \quad 6$$

F. VARIANCE OF SAMPLE SIZE OF THE SPRT.

It would appear that the Variance of the Sample Size, (N) , could be approximated in certain cases using an

⁵A. Wald, Sequential Analysis, op.cit., pp. 159-60.

⁶A. Wald, "Differentiation under the Expectation Sign in the Fundamental Identity of Sequential Analysis," Annals of Math. Stat., Vol. 17, No. 4, p. 472, December 1946.

approach similar to that for $E[N]$. During his literature review the author encountered only three references to such an approximation [Wald, 1945a], [Walker, 1950], [Cox and Roseberry, 1966a].

Since

$$V[N] = E[N^2] - E^2[N] \quad (4)$$

an approximation for $V[N]$ may be developed as follows:

$E^2[N]$ can be approximated using Eq. (3). An approximate value for the $E[N^2]$ may be derived from

$$E[Z^2 | \theta] = E\left[\left(\sum_{i=1}^N Z_i\right)^2 | \theta\right] = E\left[\sum_{i=1}^N Z_i^2 + \sum_{\substack{i=1 \\ i \neq j}}^N Z_i Z_j\right] .$$

Utilizing Wald's Fundamental Identity, this may be written

$$E[Z^2 | \theta] = E[N]E[Z_1^2 | \theta] + E[N(N-1)]E^2[Z_1 | \theta]$$

where, as before, Z_i and Z_j are independent and identically distributed. Expanding and collecting terms

$$E[Z^2 | \theta] = E[N](E[Z_1^2 | \theta] - E^2[Z_1 | \theta]) + E[N^2]E^2[Z_1 | \theta]$$

$$E[Z^2 | \theta] = E[N] V[Z_1 | \theta] + E[N^2] E^2[Z_1 | \theta] .$$

Then

$$E[N^2] = \frac{E[Z^2 | \theta] - E[N] V[Z_1 | \theta]}{E^2[Z_1 | \theta]} , \quad (5)$$

with

$$E[Z^2 | \theta] \doteq [1-L(\theta)]\text{Ln}^2 A + L(\theta)\text{Ln}^2 B \quad .$$

Using Eqs. (3) and (5) in (4), an approximate Variance of the Sample Size is thus given by

$$V[N] = \frac{E[Z^2 | \theta] - E[N]V[Z_1 | \theta] - E^2[Z | \theta]}{E^2[Z_1 | \theta]}$$

$$V[N] = \frac{V[Z | \theta] - E[N] V[Z_1 | \theta]}{E^2[Z_1 | \theta]} \quad . \quad (6)$$

Unfortunately, using Eq. (6) to calculate the approximate Variance of Sample Size leads to negative values in many cases. This appears to be caused by the magnification of the approximations used in Eq. (3) when they are entered in Eq. (5). Whether this is in fact the true cause, the approximation in general is not good. Consequently, no numerical tabulations of the $V[N]$ using Eq. (6) are included. However, empirically determined "exact" values of the $V[N]$ are included.

IV. DISTRIBUTIONS INVESTIGATED

The author investigated the SPRT for three common distributions: the Binomial, Normal, and Exponential. Each distribution was investigated for various parameter values. Each specific distribution was used in calculating the Wald "approximate" results and in generating empirical "exact" results for the OC curve, Expected Sample Size, and the Variance of Sample Size.

Explicit equations for the points on the Wald "approximate" Operating Characteristic Curve, the "approximate" Expected Sample Size Curve, and the "approximate" Variance of Sample Size Curve are given for these distributions using Eqs. (1), (3), and (6).

A. BINOMIAL DISTRIBUTION

Suppose $f(x; \theta) = \theta^x (1-\theta)^{1-x}$ the logarithm of the likelihood ratio is

$$Z_1 = \text{Ln} \left[\left(\frac{\theta_1}{\theta_0} \right) \left(\frac{1-\theta_1}{1-\theta_0} \right)^{1-X_1} \right] .$$

Then

$$\begin{aligned} E[Z_1 | \theta] &= \theta \text{Ln} \frac{f(1, \theta_1)}{f(1, \theta_0)} + (1-\theta) \text{Ln} \frac{f(0, \theta_1)}{f(0, \theta_0)} \\ E[Z_1 | \theta] &= \theta \text{Ln} \left[\frac{\theta_1}{\theta_0} \right] + (1-\theta) \text{Ln} \left[\frac{1-\theta_1}{1-\theta_0} \right] \end{aligned} \quad (7)$$

and

$$V[Z_1 | \theta] = E[Z_1^2 | \theta] + E^2[Z_1 | \theta]$$

$$V[Z_1 | \theta] = \theta(1-\theta) \left[\text{Ln} \frac{\theta_1}{\theta_0} \frac{(1-\theta_0)}{(1-\theta_1)} \right]^2 \quad (8)$$

In order to obtain an approximate OC function, the expression of Eq. (2) for this case,

$$\theta \frac{\theta_1}{\theta_0}^{h(\theta)} + (1-\theta) \left[\frac{(1-\theta_1)}{(1-\theta_0)} \right]^{h(\theta)} = 1 \quad ,$$

was solved for θ and evaluated with various selected values of $h(\theta)$,

$$\theta = \frac{1 - \left[\frac{(1-\theta_1)}{(1-\theta_0)} \right]^{h(\theta)}}{\left[\frac{\theta_1}{\theta_0} \right]^{h(\theta)} - \left[\frac{(1-\theta_1)}{(1-\theta_0)} \right]^{h(\theta)}} \quad (9)$$

Utilizing Eq. (9) with Eq. (1) points on the Wald approximate OC Curve were obtained.

By substituting Eq. (7) into Eq. (3) the Wald approximate Sample Size curve was determined. An attempt was made to determine the approximate Variance of Sample Size, utilizing Eqs. (7) and (8) with the prior results of $E[N]$, in Eq. (6).

The acceptance and rejection numbers were respectively computed from

$$A_n = \frac{\text{Ln } B + n \text{Ln } \frac{(1-\theta_o)}{(1-\theta_1)}}{\text{Ln } \frac{\theta_1}{\theta_o} - \text{Ln } \frac{(1-\theta_1)}{(1-\theta_o)}}$$

and

$$R_n = \frac{\text{Ln } A + n \text{Ln } \frac{(1-\theta_o)}{(1-\theta_1)}}{\text{Ln } \frac{\theta_1}{\theta_o} - \text{Ln } \frac{(1-\theta_1)}{(1-\theta_o)}} \quad .$$

B. NORMAL DISTRIBUTION

If $f(x; \theta)$ is Normal (θ, σ^2) then the log likelihood ratio is

$$Z_i = \frac{1}{2\sigma^2} [2(\theta_1 - \theta_o)x_i + (\theta_o^2 - \theta_1^2)],$$

and

$$E[Z_i | \theta] = \frac{\theta_o^2 - \theta_1^2}{2\sigma^2} + \frac{\theta(\theta_1 - \theta_o)}{\sigma^2} \quad (10)$$

and

$$V[Z_i | \theta] = \frac{(\theta_1 - \theta_o)^2}{\sigma^2} \quad (11)$$

Substituting Eq. (10) into Eq. (3) points on the Wald approximate Sample Size Curve were computed. Eqs. (10) and (11) with $E[N]$ computed above were used in Eq. (6) in an attempt to determine the approximate Variance of N .

In order to determine points on the approximate OC curve, the expression of Eq. (2) for the present case was solved for $h(\theta)$, resulting in

$$h(\theta) = \frac{\theta_1 + \theta_0 - 2\theta}{\theta_1 - \theta_0} \quad .$$

The acceptance and rejection numbers are, in this case, respectively given by

$$A_n = [\sigma^2/(\theta_1 - \theta_0)] \text{Ln } B + n\left[\frac{\theta_0 + \theta_1}{2}\right]$$

and

$$R_n = [\sigma^2/(\theta_1 - \theta_0)] \text{Ln } A + n\left[\frac{\theta_0 + \theta_1}{2}\right] \quad .$$

C. EXPONENTIAL DISTRIBUTION

If $f(x; \theta) = \theta e^{-\theta x}$; $x \geq 0$, the log likelihood ratio is

$$Z_1 = \text{Ln } \frac{\theta_1}{\theta_0} - (\theta_1 - \theta_0)X_1$$

so that

$$E[Z_1 | \theta] = \text{Ln } \frac{\theta_1}{\theta_0} - \frac{(\theta_1 - \theta_0)}{\theta} \quad (12)$$

and

$$V[Z_1 | \theta] = \frac{(\theta_1 - \theta_0)^2}{\theta^2} \quad (13)$$

Substituting Eq. (12) into Eq. (3), points on the Wald approximate Sample Size curve were obtained. Eqs. (12) and (13) were used in Eq. (6) in an attempt to determine an approximate Variance of N .

In order to determine values for an approximate OC curve, Eq. (2) was solved for θ , resulting in

$$\theta = \frac{h(\theta) (\theta_1 - \theta_0)}{\left[\frac{\theta_1}{\theta_0} \right]^{h(\theta)} - 1} . \quad (14)$$

Utilizing Eqs. (1) and (14) points on the Wald approximate OC Curve were obtained.

The acceptance and rejection numbers are respectively given by

$$A_n = \frac{-\ln B + n \ln \frac{\theta_1}{\theta_0}}{(\theta_1 - \theta_0)}$$

and

$$R_n = \frac{\ln A + n \ln \frac{\theta_1}{\theta_0}}{(\theta_1 - \theta_0)} .$$

V. PROCEDURE

Computer programs, coded in FORTRAN IV, were written which gives points on the Wald approximate OC Curves, and the approximate Expected Sample Size curves. Programs for the Binomial, Normal, and Exponential distributions, each entitled "Approximate (Distribution)" are listed under Computer Programs.

In order to evaluate the Wald approximations, companion programs called "exact" programs were written. These programs produce Monte Carlo simulation of the SPRT procedure for the distribution considered. Each program determines "exact" points on the OC curve, Expected Sample Size curve and Variance of Sample Size curve.

The simulation models sequential sampling from a specific known distribution with parameter values being inputs to the simulation. As each sample was observed, a corresponding acceptance and rejection number was computed and the test statistic was computed. These values were compared and the appropriate alternative was selected.

A. DETERMINATION OF THE NUMBER OF REPLICATIONS

In order for the simulation estimates of the Operating Characteristic points, $\hat{L}(\theta)$, (a Bernoulli parameter) to be useful, it is necessary to use a large number of replications (that is, simulate the performance of many tests) so that with a high probability $\hat{L}(\theta)$ is "close" to the true

$L(\theta)$. A Normal approximation to the binomial was used to determine the number of replications that should be used at each sample point. This was done as follows:

Let S_J denote the number of successes in J independent repeated Bernoulli trials with parameter p , and let

$$P_J = \frac{1}{J} S_J$$

denote the average number of successes in J trials. For large J , P_J can be shown to be approximately Normal with mean p and variance $p(1-p)/J$. Then $Y_J = (P_J - p) / [p(1-p)/J]^{1/2}$ is approximately Normal $(0, 1)$. For any level of risk, $\gamma > 0$, and minimum acceptable probability bound, $\delta > 0$, we seek J such that

$$P[P_J - p] = P\left[\left|\frac{P_J - p}{\sqrt{p(1-p)/J}}\right| \leq \frac{\gamma}{\sqrt{p(1-p)/J}}\right] \geq \delta$$

or

$$P\left[\frac{-\gamma\sqrt{J}}{\sqrt{p(1-p)}} \leq Y_J \leq \frac{\gamma\sqrt{J}}{\sqrt{p(1-p)}}\right] \geq \delta.$$

This occurs whenever

$$J \geq \frac{y_\delta^2 p(1-p)}{\gamma^2}$$

where y_δ is such that $P[Y < -y_\delta] = \frac{1-\delta}{2}$, where Y is distributed Normal $(0, 1)$. At $p = 1-p = 1/2$, $J \geq \frac{y_\delta^2}{(2\gamma)^2}$, so for $\gamma = .01$ and $\delta = .95$, $Y_\delta = 1.645$ and the required

value of J is approximately 6,765. Additionally:

$p = .1, \quad \gamma = .01, \quad \delta = .95$ requires $J = 1481$;

$p = .01, \quad \gamma = .01, \quad \delta = .95$ requires $J = 163$;

$p = .1, \quad \gamma = .01, \quad \delta = .95$ requires $J = 2095$;

$p = .3, \quad \gamma = .01, \quad \delta = .95$ requires $J = 4889$.

In view of these and similar determinations and since it was desired to estimate $L(\theta)$ values as large as .30 to within reasonable accuracy, a selection of 5000 replications for each estimation of $L(\theta)$ value was made. The values obtained in the simulation should therefore, with high probability, be accurate to at least 2, and usually 3, decimal places. A fourth decimal was carried in the tables to exclude possible round off errors.

B. COMPUTER SIMULATION

For each distribution investigated two computer programs were developed; an "approximate program" based on the Wald approximations for the SPRT, and the "exact program" involving a Monte Carlo simulation. The inputs necessary for these programs are the number of distributions to be inspected, the parameter values for the Null and Alternate Hypotheses (θ_0 and θ_1), the "target" Type I and Type II Error Probabilities (α and β), parameters for the distribution being sampled (θ), arguments for the random number generator (URN, a special random number generator included in the IBM Scientific Package at the Naval Postgraduate School), the number of replications (in this thesis 5000)

at each test point, (θ), and the number of test points from the "approximate program" being used in the "exact program." These values, punched in one input card, and the associated output from the "approximate program," which is run first, comprise the input data for the exact program.

Simulation of observations from Binomial, Normal, and Exponential distributions were by standard methods. Background information may be obtained in [Naylor, 1967] and [McMillan and Gonzalez, 1968].

In order to obtain the values tabulated in this thesis the procedure was to first run an "approximate program." These programs produce a fixed number of test points. In the Approximate Binomial program the number of test points (now 85) is controlled by the last "IF" statement in the program, varying the value 41 changes the number of test points. Control of the number of test points (80) in the Approximate Normal program is by changing the numerical multipliers in the first "XM2" and "XM" steps. Control of the number of test points (50) in the Approximate Exponential program is by changing the limit on the "DO 7" statement. The presentation of the Approximate Program output (Approximate OC Value, θ , Approximate Expected Sample Size) is a listing and a separate punched card for each test point, θ . Prior to running the "exact program," the number of test points was reduced to 15 to 20 so as to

reduce the execution time. The Exact Program output (see tables) is a listing and a set of punched cards.

"Exact" OC values of various SPRT's were estimated by the relative frequency of the number of replications terminating with acceptance of H_0 , at each of several values of θ .

"Exact" expected sample sizes at each test point, θ , were estimated by tallying, each time the test was performed, the observed sample requirement. The average sample size being computed at the end of the 5000 replications. These averages were taken to be the exact values of $E[N]$.

The "exact" variance of sample size at each test point, θ , was computed in a manner similar to that used for the $E[N]$,

$$V[N] = \frac{1}{n-1} \left[\sum_{i=1}^n m_i^2 - nE^2[N] \right],$$

where $n = 5000$ replications and m_i denotes the number of observations required in the i th simulated test.

C. COMPUTER STATISTICS.

The IBM-360 at the Naval Postgraduate School was utilized in computing the values presented. The maximum core space needed for any one of the programs was less than 58K bytes. The necessary time to complete an "approximate" case was less than 5 seconds. The "exact" programs were run under the H compiler of the IBM-360. In

certain cases this allowed an execution time savings of 80% with respect to running under the G compiler. The running time per case for the programs averaged 11 minutes as presented, with a maximum of about 15 minutes.

VI. CONCLUSIONS AND RESULTS

A comparison of the Wald "approximate" results with the "exact" results described above confirmed the known fact that, in all cases, the results obtained using the Wald approximations for the SPRT are conservative in that a given test plan's error probabilities are greater than the exact values. In the Binomial cases as much as a 22% difference in the target α level and the exact α level was noted; for the Exponential distribution in one case ($H_0 = 1.0$, $H_1 = 5.0$, $\alpha = .03$, $\beta = .05$) a 50% difference was noted, with the differences generally averaging about 25 to 30%. For the Normal distribution the percentage difference in the target α level and the exact α level appears to increase with $|\theta_0 - \theta_1|$.

A comparison of the approximate and exact expected sample sizes is facilitated by the tabilized values. In all cases the results following indicate that at each test point the "exact" expected sample size is larger than the Wald approximation.

The exact variances of sample size found here support the conjecture of [Cox and Roseberry, 1966a], namely, that $V[N]$ is approximately the square of $E[N]$. Unfortunately, as noted earlier a natural approximation for $V[N]$ turned out to yield especially poor approximations. However, the exact variance of N does appear to increase roughly as the square of $E[N]$, in the cases considered here.

In all, forty-six cases were examined. The final results of all cases are tabulated below.

ABSTRACT <p>An examination of the Wald stopping bounds for the Sequential Probability Ratio Test (SPRT) is made by comparing results obtained from Monte Carlo simulations of sequential sampling tests with results obtained using Wald formulations. Operating Characteristic, ASN, and $V[N]$ values are presented for test sampling from each of eight Binomial, 14 Exponential, and 24 Normal distributions. An extensive bibliography of references associated with SPRT is included.</p>
